Nitrate

Direct ISE Method

0.1 to 100.0 mg/L NO$_3$–N

Scope and application: For water and wastewater.

Test preparation

Instrument-specific information

This procedure is applicable to the meters and probes that are shown in Table 1. Procedures for other meters and probes can be different.

Before starting

Refer to the meter documentation for meter settings and operation. Refer to probe documentation for probe preparation, maintenance and storage information.

Prepare the probe before initial use. Refer to probe documentation.

When an Intellical probe is connected to an HQ meter or an HQd meter, the meter automatically identifies the measurement parameter and is prepared for use.

Condition the probe before use. To condition the probe, put the probe in 100 mL of the lowest concentration standard solution for a maximum of 1 hour.

Calibrate the probe before initial use. Refer to Calibration procedure on page 3.

During calibration, measure the standard solutions from lowest to highest concentration for best results.

The result is NO$_3$–N mg/L (nitrate-nitrogen) shown as elemental nitrogen (N). To change the results to NO$_3$–mg/L (nitrate), multiply the results by 4.4.

Make sure that the calibration solutions and the samples are at the same temperature (± 2 °C (± 3.6 °F)) for best results.

Stir the standards and samples at a slow and constant rate to prevent the formation of a vortex.

Air bubbles under the sensor tip can cause slow response or measurement errors. To remove the bubbles, carefully shake the probe.

Small differences in concentration between samples can increase the stabilization time. Make sure to condition the probe correctly. Try different stir rates to see if the stabilization time decreases.

A white precipitate forms if chloride or other ions are in the sample. The white precipitate will not cause damage to the probe or interfere with the analysis.

Review the Safety Data Sheets (MSDS/SDS) for the chemicals that are used. Use the recommended personal protective equipment.
Dispose of reacted solutions according to local, state and federal regulations. Refer to the Safety Data Sheets for disposal information for unused reagents. Refer to the environmental, health and safety staff for your facility and/or local regulatory agencies for further disposal information.

This procedure is specified for the HQ meters and HQd meters. The Sension+ meters can be used, but the menus and navigation will be different.

Sample collection

- Collect samples in clean glass or plastic bottles.
- Analyze the samples as soon as possible for best results.
- If immediate analysis is not possible, keep the samples at or below 6 °C (43 °F) for a maximum of 24 hours.
- If prompt analysis is not possible, adjust the sample pH to 2 or less with concentrated sulfuric acid (approximately 2 mL per liter). No acid addition is necessary if the sample is analyzed immediately. The test result will then include nitrate and nitrite.
- To preserve samples for later analysis, keep the samples at or below 6 °C (43 °F) for a maximum of 28 days.
- Let the sample temperature increase to room temperature before analysis.
- For samples preserved with acid, adjust the pH to 7 with 5 N sodium hydroxide solution before analysis.
- Do not use mercury compounds as preservatives.
- Correct the test result for the dilution caused by the volume additions.

Test procedure

1. Add 25 mL of sample to a beaker.
2. Add the contents of one Nitrate ISA Powder Pillow.
3. Add a stir bar and put the beaker on a magnetic stirrer. Stir at a moderate rate.
4. Rinse the probe with deionized water. Dry the probe with a lint-free cloth.
5. Put the probe in the solution. Do not let the probe touch the stir bar, bottom or sides of the container. Remove the air bubbles from under the probe tip.

6. Push **Read**. A progress bar is shown. When the measurement is stable, the lock icon is shown.

7. Rinse the probe with deionized water. Dry the probe with a lint-free cloth.

---

**Calibration**

1. Add 25 mL of the lowest concentration standard solution to a beaker.

2. Add the contents of one Nitrate ISA Powder Pillow.

3. Add a stir bar and put the beaker on a magnetic stirrer. Stir at a moderate rate.

4. Rinse the probe with deionized water. Dry the probe with a lint-free cloth.

5. Put the probe in the solution. Do not let the probe touch the stir bar, bottom or sides of the container. Remove the air bubbles from under the probe tip.

6. Push **Calibrate**. The standard solution value is shown.

7. Push **Read**. A progress bar is shown. When the measurement is stable, the lock icon is shown.

8. Rinse the probe with deionized water. Dry the probe with a lint-free cloth.
9. Measure the remaining standard solutions.

10. Push Done. A calibration summary is shown when the minimum number of calibration standards are measured.

11. Push Store to accept the calibration.

Low-level measurements

Use the techniques that follow for measurements at low concentrations (<1 mg/L).

- Clean the probe regularly. Refer to Clean the probe on page 6.
- Soak the probe in the lowest concentration standard solution for a maximum of 1 hour before calibration and measurement.
- Set the stability criteria in the settings menu to a low value (for applicable meters and probes).
- Use a dilute ionic strength adjustor (ISA) solution for calibration and measurements:
  1. Dissolve the contents of one ionic strength adjustor powder pillow in 50 mL of deionized water.
  2. Add 5 mL of this solution to every 25 mL of standard or sample that is used.

Note: The use of the ISA is optional when the conditions that follow are true:

- The sample does not contain interferences.
- The sample pH is in the range that is given in the electrode specifications.
- Omission of the ISA is accepted by the regulatory reporting agency (if applicable).

Interferences

The sensing element responds to nitrate as well as other ions. Typically, probe response to another ion increases the potential, and causes a positive error. The response to other ions can be semi-quantitatively determined through the Nikolsky equation, an extended Nernst equation:

\[ E = E^0 + \frac{RT}{ZF} \ln(a_{Na} + K_{Na} \times ax) \]

Where:

- ax—The activity of the interfering ion
- KNa—The selectivity coefficient for the interfering ion relative to nitrate

For the nitrate ISE, the major interferences are shown in Table 2. To eliminate most of these interferences, add the Nitrate ISA and adjust the pH to between 3 and 5. The measurements are usually made at this pH range to eliminate carbonate and bicarbonate interference and reduce organic acid interference.

The selectivity coefficient is the approximate apparent increase in the measured concentration caused by one unit of the interfering ion (e.g., 1 unit of ClO₄⁻ raises the nitrate concentration by 0.1). The approximate selectivity coefficients for some ions with the IntelliCAL® Nitrate ISE are shown in Table 2.
Table 2  Interfering substances

Accuracy check

Slope method

Use the slope method to validate the electrode response.

1. Prepare two standard solutions that are one decade apart in concentration (e.g., 1 mg/L and 10 mg/L or 10 mg/L and 100 mg/L). The minimum concentration is 0.2 mg/L.
2. Use the test procedure to measure the mV value of each standard solution.
3. Compare the mV value of each standard solution. The expected difference is 58 (± 3) mV at 25 °C (77 °F).

Standard solution method

Use the standard solution method to validate the test procedure, the reagents (if applicable) and the instrument.

Items to collect:
- Standard solution within the test range

1. Use the test procedure to measure the concentration of the standard solution.
2. Compare the expected result to the actual result.

Standard additions method

Use the standard additions method to validate the test procedure, reagents and instrument and to find if there is an interference in the sample.

Items to collect:
- Nitrate Nitrogen Standard Solution, 100 mg/L
- Graduated cylinder, 25 mL, polypropylene
- TenSette pipet
- Pipet tips

1. Use a graduated cylinder to measure 25 mL of sample into a beaker.
2. Use the test procedure to measure the concentration of the sample.
3. Use the TenSette pipet to add 0.5 mL of the standard solution to the sample.
4. Measure the concentration of the spiked sample.
5. Compare the results before and after the standard solution addition. The concentration should increase by 1.96 mg/L NO₃⁻-N.

Temperature check

For probes that do not have a temperature sensor, measure the temperature of the standard solutions and samples. Make sure that the calibration solutions and the samples are at the same temperature (± 2 °C (± 3.6 °F)) for best results.
Clean the probe

Clean the probe when:

• Drifting/inaccurate readings occur as a result of contamination on the sensing element or incorrect storage conditions.
• Slow response time occurs as a result of contamination on the sensing element.
• The slope is out of range as a result of contamination on the sensing element.

For general contamination, complete the steps that follow.

1. Rinse the probe with deionized water. Blot dry with a lint-free cloth.
2. If harsh contaminants are attached to the probe, polish the probe tip with a soft cloth or cotton swab to remove the contaminants.
3. Soak for 30 minutes in 100 mg/L Nitrate Nitrogen Standard Solution. Rinse the probe with deionized water. Blot dry with a lint-free cloth. Install the sensor protection cap on the probe.

Summary of method

Nitrate ions are selectively absorbed by the ISE membrane. The absorbed nitrate ions cause a potential (voltage) that is proportional to the concentration of nitrate in the sample. The ISE membrane is a solvent-polymer membrane that is a nitrate ion-exchanger in an inert polyvinyl chloride (PVC) plastic matrix. The nitrate electrode has an internal silver/silver chloride element, which results in a fixed-reference potential when it touches the internal filling solution.
